

# **Analysis of whistler weather data**

*Snowfall patterns, related variables and odd behavior*

by Nathan Esau, Ethan Sim, Benjamin Chan

## Summary

### Background

In this study we analyze daily weather data from Whistler, BC. The variables analyzed were the amount of snow on the ground and the average temperature during each day.

Our study was motivated by trying to answer the following questions:

1. When is the winter season? When does it start, peak and end?
2. How severe is the winter? How much snow is present at different points in the year?
3. What trends exist in the data? What odd behaviors have shown up over the past 9 years?

### Methods

To answer our questions, we used the following techniques:

1. Regression, to determine whether there was a trend in the snowfall data
2. Time series techniques, such as average smoothing, to compare different winter seasons
3. Correlation, to determine how different variables were related

### Results

We found that while temperature is very consistent year to year, the amount of snowfall has been showing a downward trend. In particular, the 2009–2010 winter in which Vancouver hosted the Olympics was far less severe, both in the amount of snow and the duration of snowfall, than typical winter seasons. This was shown by comparing the length, average snowfall and peak snow amount of the 2009–2010 winter to other winters.

By averaging different annual time series, we determined what a typical winter season is like in Whistler. In order to do so, we needed to make an assumption about what constitutes the start and end of winter. We classified winter as the period when the average snow on the ground over a week stayed above a given threshold. This contrasts the typical definition of winter as the period from December 21 to March 21.

We also analyzed whether cold winters also tend to have a lot of snow. While these variables do exhibit some negative correlation, we do not have too much evidence that this is necessarily the case.

### Interpretation

Whistler weather typically ranges from ...

## Introduction

Our whistler weather data was obtained from <http://climate.weather.gc.ca/>. Data was recorded at an elevation of 657.80 metres, a longitude of 122°57'17.400" W and a latitude of 50° 07'44.001" N over the period 2006 – 2014. The data set contained the following variables

- Temperature – minimum, maximum and mean temperature during each day
- Snow on the ground
- Total precipitation
- Wind speed and direction

The variables most relevant to answering our questions were the snow on the ground and the temperature. For temperature, we decided to use the mean temperature during each day, as we felt this is the most robust measure. We didn't account for wind, due to the large number of missing and truncated values present, or for precipitation which we felt wasn't related to our question.

We needed to perform some imputation for our variables. In particular, the snow on the ground during the summer months was not recorded, so we made the assumption that there was no snow on the ground at this point. Also, during the winter period when snow was not recorded we imputed the snow value from the previous day. Similarly, when the temperature was not recorded we imputed the temperature value from the previous day. During the winter, there was a small amount of missing values for these variables (< 5%) so this imputation shouldn't have a large impact on our analysis.

Our overall goal was to understand the time series shown in Figure 1.

Whistler Blackcomb is a Canadian resort town in the province of British Columbia, Canada, one of the largest ski resorts in North America. Whistler's economy is highly dependent on the seasonality of snow as the main activities offered are skiing and snowboarding. In July 2003, Whistler was selected as the winning bid for the 2010 Winter Olympics to host the alpine skiing events. However, 2010 was accompanied with an unusually mild winter, setting an alarming lack of snow coverage for the smooth running of the Winter Olympics activities. Given such uncertainty, it would be helpful to have a rough estimate of when the winter season would be starting and the peak time of snowfall.

This paper establishes an exploratory data analysis on estimating the start and length of the winter season, as well as the peak of the snowfall.

## Methods

### Trend

The trend for snowfall is shown in Figure 2.

The average time series are shown in Figure 3. Nulla malesuada porttitor diam. Donec felis erat, congue non, volutpat at, tincidunt tristique, libero. Vivamus viverra fermentum felis. Donec nonummy pellentesque ante. Phasellus adipiscing semper elit. Proin fermentum
